Linear Stability Analysis

analytically for shell

# Transitions in convective regimes (2)

Changes in vertical flow structures

(Solomatov, 1995)

Three convective regimes are identified depending on the temperature-dependence of viscosity:

❑ “Whole-Layer” (WH) mode

(for weak dependence)

thin cold thermal boundary layer is involved into convection at depth.

❑ Transitional mode (for moderate dependence)

❑ “Stagnant-Lid” (ST) mode

(for strong dependence)

thick and stiff cold thermal boundary layer (or “lid”) is NOT involved into convection at depth.

Discussion and Concluding Remarks

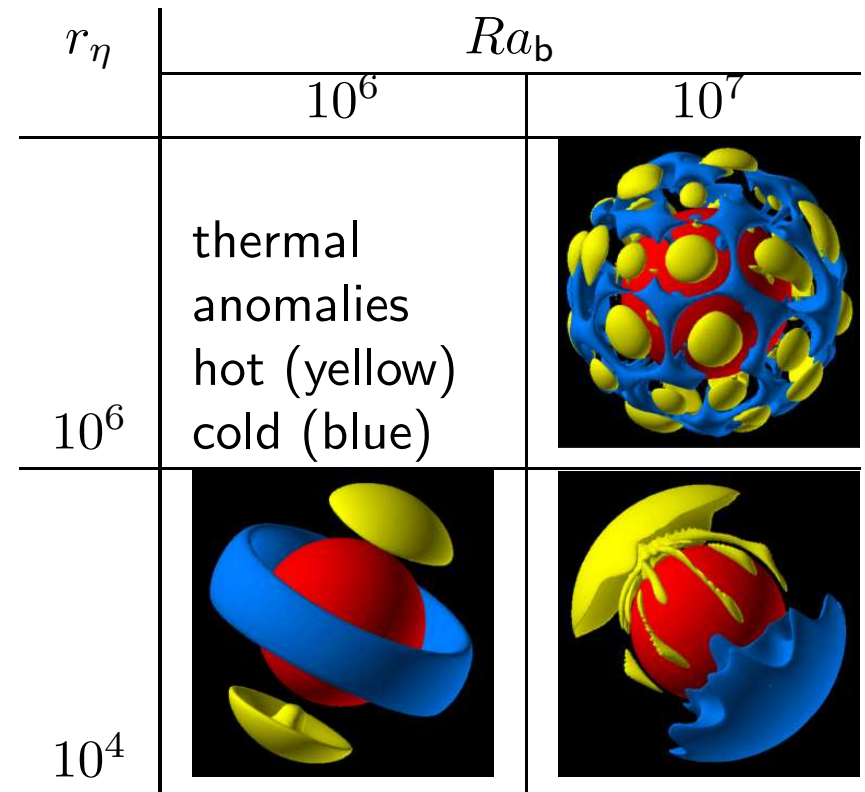

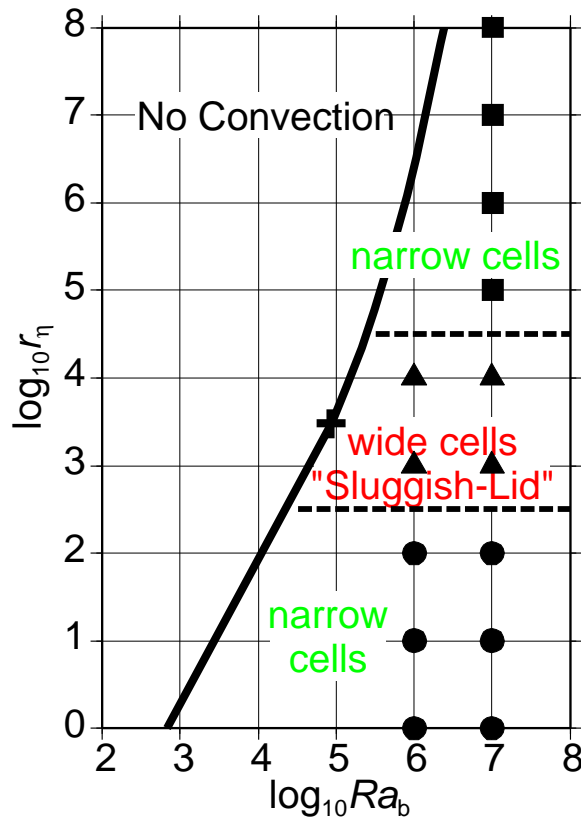

Linear Stability Analysis

analytically for shell

❑ What is the relation between the changes in vertical and horizontal flow structures ?

❑ How convection looks when viscosity is strongly temperature-dependent ?

Is it always characterized by convection cells of small horizontal length scales beneath cold stiff lids ?

❑ If not, under which conditions does convection simultaneously have **cells of large horizontal length scales** and **cold stiff lids** ?

Results 3 :  $\eta(T)$  in a spherical shell

Discussion and Concluding Remarks

Linear Stability Analysis

analytically for shell

- Equation of heat transport

$$\frac{\partial T}{\partial t} + \underbrace{\mathbf{v} \cdot \nabla T}_{\text{advection}} = \underbrace{\nabla^2 T}_{\text{conduction}}$$

- Equation of continuity (incompressible fluid)

$$\nabla \cdot \mathbf{v} = 0$$

- Equations of motion (force balance)

$$0 = -\nabla p + \nabla \cdot [\eta (\nabla \otimes \mathbf{v} + \mathbf{v} \otimes \nabla)] + RaT \mathbf{e}_g$$

- Constitutive Equation (temperature-dependence of viscosity)

$$\eta = \eta_{1/2} \exp \left[ -E \left( T - \frac{1}{2} \right) \right]$$

where  $Ra$  : Rayleigh number (defined with  $\eta_{1/2}$ , not with  $\eta_b$ )  
 $E$  : temperature-dependence of viscosity

In this study, **linearized equations** are solved for infinitesimal perturbations in  $T$  and  $\mathbf{v}$ .

Results 3 :  $\eta(T)$  in a spherical shell

Discussion and Concluding Remarks

Linear Stability Analysis

analytically for shell

For very strong temperature-dependence (large  $E$ ),

- ❑ differences in top surface boundary conditions become negligibly small.
- ⇒ almost zero motion even with free-slip top boundaries.

# Analytical Criterion for ST-mode (1)

Following the idea by Stengel *et al.* (1982) ....

In ST regime, convection begins in a basal sublayer, not in an entire layer.

For sufficiently large  $E$ , the Rayleigh number  $\hat{Ra}$  local to the basal sublayer exceeds  $Ra$  for the entire layer.

Results 3 :  $\eta(T)$  in a spherical shell

Discussion and Concluding Remarks

Linear Stability Analysis

analytically for shell

Consider the ratio of sublayer's  $\hat{Ra}$  to  $Ra$ , in order to confirm the transition into ST regime at  $E \simeq 8$ .

$$\frac{\hat{Ra}}{Ra} = \frac{\boxed{\text{thickness}}^3 \times \boxed{T\text{-gap}}}{\boxed{\text{viscosity}}} = \hat{z}^4 \exp \left[ E \left( \frac{1}{2} - \frac{\hat{z}}{2} \right) \right]$$

When  $E > 8$  there exists a range of  $\hat{z} (< 1)$  which allows  $\hat{Ra} > Ra$ .

Convective instability tends to grow only in a basal sublayer with  $\hat{Ra} > Ra$

$\Rightarrow$  "Stagnant-Lid" mode

Results 3 :  $\eta(T)$  in a spherical shell

Discussion and Concluding Remarks

Linear Stability Analysis

analytically for shell

Above analytical consideration also suggests that  $Ra$  for the entire layer should be maximum at the transition into ST regime.

The plots for free-slip top surfaces (F/F and F/R) have maxima at around  $E = 8.3$ .

⇒ Transition into ST regime occurs at  $E \simeq 8.3$  for a planar layer.

Results 3 :  $\eta(T)$  in a spherical shell

Discussion and Concluding Remarks

Linear Stability Analysis

analytically for shell

Vertical profiles of  $|\Delta_h|$  for various  $E$   
As for a local maximum other than at  $z = 0$ ,

- ❑ Where does it occur?
- ❑ How large is it ?

The local maximum of  $|\Delta_h|$  occurs at deeper position with increasing  $E$ .

At transition into ST regime ( $E = 8.3$ ), the local maximum becomes more than 10 times larger than  $|\Delta_h|$  at  $z = 1$ .

⇒ to be used as a criterion for a spherical shell convection.

(b) ■ ( $r_{\eta} = 10^6$ )

(c) ▲ ( $r_{\eta} = 10^4$ )

For the value of  $r_{\eta} = 10^4$  at the transition into ST regime, convection has horizontally-elongated cells.

wide convection cells beneath cold stiff lids at  $r_{\eta} \simeq 10^4$  ?

# ST-mode of convection with elongated cells

## “Elongated-ST” mode

(figure and movie modified from Kameyama and Ogawa, 2000)

$$Ra_b = 6 \times 10^6, r_\eta = 10^4, \text{width/height}=3$$

21

- ❑ horizontally-elongated convection cell
- ❑ minor descending plumes from base of cold lid
  - ⇒ cold lid is stiff enough to prevent minor instabilities from penetrating upward.

Linear Stability Analysis

analytically for shell

How come the convective flows with **wide cells beneath cold stiff lids** in mantles of terrestrial planets ?

In particular,

what mechanisms cause **convection cells of large horizontal length scales** ?

Hopefully, graduate students will address:

- ❑ the effects of **material properties** (other than viscosity) ?
  - ⇒ thermal expansivity, thermal conductivity, .... ?
- ❑ the effects of **chemical heterogeneity** (and surface tectonics) ?
  - ⇒ If ascending plumes are “anchored” by chemical “piles” in the lowermost mantle ?

Split all quantities into the sum of

- reference state (denoted by overbars)
- infinitesimal perturbation (denoted by primes)

$$T = \bar{T} + T', \quad \mathbf{v} = \bar{\mathbf{v}} + \mathbf{v}', \quad p = \bar{p} + p'$$

Choice of reference state

- $\mathbf{v} = \mathbf{0}$  (motionless)
- $0 = \nabla^2 \bar{T}$  (1-D steady heat conduction)

$$0 = \frac{d^2 \bar{T}}{dz^2} \text{ for a planar layer,}$$

$$0 = \frac{1}{r^2} \frac{d}{dr} \left( r^2 \frac{d\bar{T}}{dr} \right) \text{ for a spherical shell,}$$

Derive linearized equation for infinitesimal perturbations  
Dropping the second-order terms yields

- Equation of heat transport

$$\frac{\partial T'}{\partial t} + \mathbf{v}' \cdot \nabla \bar{T} = \nabla^2 T'$$

- Equation of continuity (incompressible fluid)

$$\nabla \cdot \mathbf{v}' = 0$$

- Equations of motion (force balance)

$$0 = -\nabla p' + \nabla \cdot [\bar{\eta} (\nabla \otimes \mathbf{v}' + \mathbf{v}' \otimes \nabla)] + RaT' \mathbf{e}_g$$

thin shell ( $\gamma = 0.95$ )

thick shell ( $\gamma = 0.55$ )

In contrast to a planar case, the maxima of  $Ra_{c0}$  against  $E$  do not necessarily indicate the transition into ST regimes.

By using appropriately defined Rayleigh number  $Ra_*$ , we will explore the analytical estimate for the transition.

Key assumption:

(a)  $r_*$  and  $T_*$  (in entire layer)      (b)  $r_{2*}$  and  $T_{2*}$  (in lower sublayer)

The temporal evolution of perturbation is assumed to be sensitive to the **viscosity of  $T = T_*$  at  $r = r_*$  where the radial temperature gradient is equal to an average temperature gradient across the entire layer.**
